Effect of Beta Glucosidase Inhibitor from Lichen Extract in Microcrystalline Cellulose Preparation from Water Hyacinth (Eichhornia crassipes)

Citra Bonnita Putri1, Sutriyo2, Herman Suryadi1,*

ABSTRACT

Objective: Microcrystalline cellulose (MCC) is an excipient commonly used in the manufacturing of pharmaceutical preparations, especially tablet. MCC has been successfully made from water hyacinth (Eichhornia crassipes) through enzymatic hydrolysis process. This study aimed to find the effect of β-glucosidase inhibitor from lichen extract to the yield of MCC, the optimum conditions of enzymatic hydrolysis including pH and reaction time and characteristics of MCC obtained compared to reference, Avicel PH-101.

Method: The study was began with extraction of cellulose enzyme and followed by determination of optimum beta-glucosidase inhibitor concentration. Then, this conditions were used for enzymatic hydrolysis of α-cellulose to MCC, followed by identification and characterization of MCC obtained and compared with Avicel PH-101.

Results: The optimum concentration of inhibitor was 120 ppm. A little higher yield of MCC was obtained when inhibitor extract is used in hydrolysis alpha-cellulose to MCC. The identity of MCC obtained was similar to infrared spectrum of reference. Other characteristics of MCC obtained were powder in the form of a slightly coarse, odorless and tasteless and slightly yellowish than reference.

Conclusion: Addition of extract of Beta glucosidase inhibitor did not improve the MCC yield significantly, but identity and characteristics of MCC obtained showed similarities to the microcrystalline cellulose reference (Avicel PH = 101).

Key words: β-glucosidase inhibitor, Enzymatic hydrolysis, Lichen extract, Microcrystalline cellulose, Water hyacinth.

INTRODUCTION

Cellulose is the most abundant organic polymer in nature which can be hydrolyzed to glucose by microbial enzymes. Water hyacinth has a relatively high cellulose content, which is up to 60%. This makes water hyacinth potentially useful as a new cellulose source.

One form of cellulose is microcrystalline cellulose (MCC). MCC is widely used in the pharmaceutical industry as a tablet filling material. Based on the research that has been carried out, cellulose derived from the stem can be a source of MCC, and has relatively similar characteristics to the characteristics of Avicel PH-101 as a comparison.

In previous studies, cellulase tests were carried out on several types of mold isolates with Trichoderma reesei as a positive control. Based on the results of cellulase activity screening using DNS-spectrophotometric reduction sugar method, the cellulase enzyme work from Trichoderma reesei has not been optimal. This is due to the very high activity of β-glucosidase. Cellulase enzyme performance can be improved by accepting β-glucosidase activity inhibitors from lichen.

In this study, the method of making MCC from water hyacinth was specifically carried out by giving inhibitors of β-glucosidase derived from lichens. The yield of MCC will be compared with MCC as results of enzymatic hydrolysis that are not given β-glucosidase inhibitors. MCC will be identified, characterized and compared to commercially available MCC (Avicel PH-101).

MATERIALS AND METHODS

Sample and chemical materials

Raw materials used in this study were water hyacinth powder obtained from Balai Tanaman Obat dan Rempah (BALITRO). Sources of lichen as potential β-glucosidase inhibitors were obtained from Curug Tilu Leuwi Opat, West Java. Trichoderma reesei as cellulase enzyme were obtained from IPB Culture Collection (IPBCC). Reagents used in this study were Dinitro Salicylic Acid (Sigma-Aldrich, USA). Other reagents and chemicals used in the study were technical.

Cellulase enzyme extraction

Extraction started with making spore suspension by adding sterile water into a test tube containing a culture stock of cellulolytic isolates. Then, it was scratched until the spores dissolved in the sterile water. A total of 10 mL of suspension of the spore and 10 mL of 0.1% of Tween 80 were fed into 200 mL of nutrient solution. Then stirred at 150 rpm for 2 h at room temperature. A mixture of 30 mL was taken and centrifuged at 3000 rpm for 10 min. From centrifugation results obtained supernatant used as a rough enzyme for screening cellulase activity.

Evaluation of β-glucosidase inhibitors and enzymatic hydrolysis of cellulose into microcrystalline cellulose.2

β-glucosidase inhibitor extraction and evaluation

The lichens are rinsed to remove dirt, left at room temperature for 24 h and cut into pieces. The lichens were extracted by maceration method using 1 L ethyl acetate solvent for 72 h with solvent replacement every 24 h. Then, the extraction results are mixed together and evaporated at room temperature. Lichen extract was diluted in a concentration of 1000 ppm using acetate buffer and concentration variations were made, namely 40; 60; 80; 100; 120 and 140 ppm.

Evaluation of cellulase activity from Trichoderma reesei based on clear zones in CMC media was carried out by cellulase degradation test method. To know the effect of β-glucosidase inhibitors, 2.5 μL of crude enzyme extract and 2.5 μL of lichen extract with a concentration of 40 ppm were injected into a petri dish containing CMC, NaNO3, KH2PO4, KCl, MgSO4.7H2O media, yeast extract and glucose. The petri dishes are then incubated at 27-28°C for 3-7 days. For comparison, the media with enzyme extracts were tested without the addition of lichens extract. The clear zone formed around the paper disc shows cellobiolytic activity.

Preparation of α-cellulose isolation

A total of 300 g of sifted water hyacinth powder then placed in a beaker glass was added with 4 L of 3.5% nitric acid (containing 40 mg sodium nitrite) and heated for 2 h at 90°C above the water bath. After that, the residue is filtered and washed with water. The residue is then immersed in 3 L of a solution containing Sodium Hydroxide and Sodium Sulphite each 2% w/v and heated at 50°C for 1 h. Then the residue is filtered and washed with water. Bleaching with 2 L of water solution with 3.5% Sodium Hypochlorite 1:1 and boiled for 10 min followed by filtration and washing of residues using water. The obtained residue was added with 17.5% w/v NaOH then heated for 30 min at 80°C, after which it was filtered and washed again with water. The resulting residue is α-Cellulose. The extraction was continued by mixing α-Cellulose in 2 L water mixture and 3.5% 1:1 Sodium Hypochlorite which was heated at 100°C for 5 min. The residue is filtered and washed thoroughly. Then dried in an oven with a temperature of 60°C and obtained α-cellulose powder.3

Method of cellulose enzyme microcrystalline cellulose preparation by hydrolysis

The 10 g α-Cellulose was hydrolyzed enzymatically with 0.05 M Sodium Acetate buffer pH 7 of 100 mL while adding a mixture of cellulase enzyme with 5 mL inhibitor at 30°C and 160 rpm for 2 h above water-shaking incubator. Thereafter, the mixture was centrifuged at 5,500 rpm (at a temperature of 7-10°C for 30 min). The rest of the enzyme was removed by washing residue that settled with the aquades then dried.

Identification and characterization

The identification was performed using FTIR (Shimadzu FTIR-8400s) to determine the functional groups present in microcrystalline cellulose samples compared to the Avicel PH 101 standard.

Scanning electron microscope (SEM)

The sample was inserted into a room then irradiated with a 10 kV electron beam so that the sample ejected detectable secondary electrons, detonating electrons and a detector scintor, which was then reinforced with an electrical circuit causing a CRT (Cathode Ray Tube) image. Shooting was done after selecting a certain part of the object (sample) and magnification was desired so that obtained a good and clear photograph. Identification was compared to Avicel PH 101.

X-Ray diffractometer (XRD)

The sample was printed on a circular plate mold and flattened until no wave is formed on the sample surface. Measurements were made using XRD Bruker D8 Advance ECO Diffractometer operated in reflection method (40 kV, 35 mA) using Cu-Kα radiation (11 = 1.54060 Å and 12 = 1.54439 Å) and using step scan method with initial position ("20) of 5,000°, step size ("20) of 0.020° (76.8 s per step) and ending at ("20) of 80.009°. The resulting diffraction pattern was compared to Avicel PH 101.

Particle size and distribution analysis

Preparation was done by dispersing the crystal powder in an appropriate medium which can disperse the sample powder. In this test, ethanol dispersion medium was used. Requirements for particle size distribution testing ranged from 0.01–200 μm.

pH test, ash content and starch test

The method used in this test is based on the Farmakope Indonesia 2014.5

Water content and organoleptic

Moisture content was measured using moisture content (Adam) with a temperature of 105°C. A number of samples were weighed ± 1.0 g on the aluminum plate that had been previously held. Then the appliance is turned on and the tool will measure the water content of the sample. The experiment is repeated using the Avicel PH 101 standard. A good microcrystalline cellulose powder is a white, odorless and tasteless powder.

Particle density

The density test of powder particles is done by bulk-tapped density. First, the product produced is weighed to meet ± 60% of the 50 m cubic density measurements. In this test, the mixture was stretched to meet ± 60% of the 50 m cubic density measurements. In this test, the mixture was stretched to meet ± 60% of the 50 m cubic density measurements. In this test, the mixture was stretched to meet ± 60% of the 50 m cubic density measurements. In this test, the mixture was stretched to meet ± 60% of the 50 m cubic density measurements.
centrifugation results obtained a supernatant crude cellulase enzyme in which the pellets are formed like thin of thread. The supernatant obtained was then used for evaluation of the action of β-glucosidase inhibitor, quantitative screening, optimization for enzymatic hydrolysis and enzymatic hydrolysis of cellulose microcrystalline.

**Evaluation of β-glucosidase inhibitors**

Screening results using Spectrophotometer UV-Vis show that increasing the concentration of lichens extract has the effect of decreasing glucose concentration. Based on these results, the extract of lichens with 120 ppm concentration was used to optimize hydrolysis conditions and a-cellulose enzymatic hydrolysis. This concentration is considered optimum because the lowest glucose concentration produced. In addition, differences in glucose levels produced at 120 ppm and 140 ppm extracts of crusty moss extract were not significant.

**Preparation of α-cellulose from water hyacinth (Eichhornia crassipes)**

The results obtained from the preliminary process are then weighed and crushed to a fine powder. But in the process, found some difficulties that is difficult to clean the powder because the original color of dark green dust so the color of the powder of the insulation results are less white, while the expected color is white. In addition to the washing process, this can occur due to lack of perfect in the process of delignification. After being isolated the dried powder is very difficult to make into microcrystalline cellulose (Avi cel PH-101 standard). Sharp peaks in microcrystalline cellulose samples are less white, while the expected color is white. In addition to the washing process, this can occur due to lack of perfect in the process of delignification. After being isolated the dried powder is very difficult to make into microcrystalline cellulose (Avi cel PH-101 standard).

**Making microcrystalline cellulose with enzymatic hydrolysis method by cellulase enzyme and β-glucosidase inhibitor**

Manufacture of microcrystalline cellulose by enzymatic hydrolysis method of cellulase enzyme with addition of inhibitor compared with enzymatic hydrolysis of cellulose enzyme without addition of inhibitor. When compared, without addition of inhibitor showed 63% yield and a little higher yield (70%) was obtained with the addition of inhibitor (data not shown).

**Identification using FTIR**

Based on the literature (Azubuik and Okhamafe, 2012), the main peaks in the infrared spectrum of microcrystalline cellulose are among 3500 - 3300 cm⁻¹ (OH), 2900 - 2800 cm⁻¹ (CH aliphatic), 1650 cm⁻¹ (-O) - drag the neighboring hydrogen atom), 900 cm⁻¹ (β-glycosidic bond) and 1060 cm⁻¹ (C-OH).¹

**Scanning electron microscope (SEM)**

SEM test results showed the formation of microcrystals in microcrystalline cellulose samples. At 500x magnification, it can be seen that microcrystalline cellulose samples have similar morphology with Avicel PH-101 standard.

**Analysis of X-Ray diffractometer (XRD)**

Avicel PH-101 standard diffractogram shows two peaks. Sharp peaks at 20 22.71 indicate the presence of crystalline polymers and the peak widened at 20 18.77 indicates the presence of amorphous polymers in the standard. Sharp peaks in microcrystalline cellulose samples at 20 20.17 and 21.89 show the crystalline part of the sample. The peak widened at 20 18.10 indicating the presence of amorphous parts in the sample. The peak doublet that appears on the crystalline part of the sample indicates the change from polymorphic cellulose I to polymorphic cellulose II which can be caused by exposure between the powder that has been bleached with 17.5% (w / v) sodium hydroxide solution when isolating α-cellulose. The discovery of doublet peaks in the crystalline part also occurs in microcrystalline cellulose produced from oil palm fibers (Xiang, Mohammed and Baharuddin, 2016) and corn cob (Azubuik and Okhamafe, 2012).² Based on the results of the diffractogram, the standard crystallinity (CI) and sample index values were known, ie 67.11% for Avicel-PH 101 standard and 79.08% for microcrystalline cellulose samples (Table 1).

**Characterization**

As seen in Table 2. (Figures 1-3 and Table 3).

**DISCUSSION**

The β-glucosidase inhibitor was extracted from lichen with maceration method with ethyl acetate as solvent. The process took 72 h with solvent changing every 24 h. The solvent then filtered and the filtrate was evaporated. The extract was made into six different concentration (20, 40, 60, 80, 100, 120, 140 ppm) that were tested with DNS assay using spectrophotometer UV-Vis. The result showed that the lichen has β-glucosidase inhibitor activity and from six concentration, 120 ppm concentration is chosen for the next process. The process continued with cellulase enzyme extraction.

Putri, et al.: Effect of Beta Glucosidase Inhibitor from Lichen Extract in Microcrystalline Cellulose Preparation from Water Hyacinth (*Eichhornia crassipes*)

Manufacture of MCC by enzymatic hydrolysis method with inhibitor was compared with enzymatic hydrolysis without inhibitor, with results that yield of enzymatic hydrolysis method with inhibitor was higher than without inhibitor. Characterization of MCC samples showed that organoleptic test, starch test, moisture content, acidity degree, drying rate and flow rate test has met the existing requirement. But for ash level test, the test results do not meet the requirements because there are still a lot of residues of inorganic compounds derived from plants water hyacinth. For particle density test and angle...
of repose, the results of microcrystalline cellulose powder samples fall into the excellent category.

**CONCLUSION**

The extract of potential lichens has β-glucosidase inhibitor properties and can increase the yield of α-cellulose enzymatic hydrolysis by up to 7%. The optimum condition of cellulase enzyme hydrolysis by extracting lichen β-glucosidase inhibitors using α-cellulose substrate from water hyacinth is at pH 7 and duration of 4 h.

The results of identification with FTIR showed similarities between microcrystalline cellulose from water hyacinth with standard; organoleptic cellulose microcrystalline from water hyacinth is similar to the standard but more yellowish in color; analysis with SEM shows the existence of morphological equations; analysis with XRD shows a crystallinity index of 67.11%; PSA analysis showed particle size diameter of 2.01 μm; qualitative analysis, acidity level, starch test, moisture content, drying shrinkage test meet the requirements; ash content does not meet the requirements; particle density test, flow rate test and break angle test meet the requirements.
